Spring 2023

## Key Agreement

Instructor: **Nikos Triandopoulos**

# Number theory background

# Multiplicative inverses

The residues modulo a positive integer  $n$  comprise set  $Z_n = \{0, 1, 2, \dots, n - 1\}$

- ◆ let  $x$  and  $y$  be two elements in  $Z_n$  such that  $x y \bmod n = 1$ 
  - ◆ we say:  $y$  is the multiplicative inverse of  $x$  in  $Z_n$
  - ◆ we write:  $y = x^{-1}$
- ◆ example:
  - ◆ multiplicative inverses of the residues modulo 11

$x$	0	1	2	3	4	5	6	7	8	9	10
$x^{-1}$		1	6	4	3	9	2	8	7	5	10

# Multiplicative inverses (cont'ed)

## Theorem

An element  $x$  in  $Z_n$  has a multiplicative inverse iff  $x, n$  are relatively prime

◆ e.g.

◆ the only elements of  $Z_{10}$  having a multiplicative inverse are 1, 3, 7, 9

x	0	1	2	3	4	5	6	7	8	9
$x^{-1}$		1		7				3		9

## Corollary

If  $p$  is prime, every non-zero residue in  $Z_p$  has a multiplicative inverse

## Theorem

A variation of Euclid's GCD algorithm computes the multiplicative inverse of an element  $x$  in  $Z_n$  or determines that it does not exist

# Euclid's GCD algorithm

Computes the greater common divisor by repeatedly applying the formula

$$\text{gcd}(a, b) = \text{gcd}(b, a \bmod b)$$

◆ example

◆  $\text{gcd}(412, 260) = 4$

a	412	260	152	108	44	20	4
b	260	152	108	44	20	4	0

**Algorithm** **EuclidGCD(a, b)**

**Input** integers **a** and **b**

**Output** **gcd(a, b)**

**if** **b = 0**

**return** **a**

**else**

**return** **EuclidGCD(b, a mod b)**

# Extended Euclidean algorithm

## Theorem

If, given positive integers  $a$  and  $b$ ,  $d$  is the smallest positive integer s.t.  $d = ia + jb$ , for some integers  $i$  and  $j$ , then  $d = \gcd(a, b)$

### ◆ example

- ◆  $a = 21, b = 15$
- ◆  $d = 3, i = 3, j = -4$
- ◆  $3 = 3 \cdot 21 + (-4) \cdot 15 = 63 - 60 = 3$

### Algorithm **Extended-Euclid**( $a, b$ )

**Input** integers  $a$  and  $b$

**Output**  $\gcd(a, b)$ ,  $i$  and  $j$   
s.t.  $ia + jb = \gcd(a, b)$

**if**  $b = 0$

**return**  $(a, 1, 0)$

$(d', x', y') = \text{Extended-Euclid}(b, a \bmod b)$

$(d, x, y) = (d', y', x' - [a/b]y')$

**return**  $(d, x, y)$

# Computing multiplicative inverses

Fact

- ◆ given two numbers **a** and **b**, there exist integers  $x, y$  s.t.

$$\mathbf{x} \mathbf{a} + \mathbf{y} \mathbf{b} = \gcd(\mathbf{a}, \mathbf{b})$$

which can be computed efficiently by the extended Euclidean algorithm

Thus

- ◆ the multiplicative inverse of  $a$  in  $Z_b$  exists iff  $\gcd(a, b) = 1$
- ◆ i.e., iff the extended Euclidean algorithm computes  $x$  and  $y$  s.t.  $\mathbf{x} \mathbf{a} + \mathbf{y} \mathbf{b} = \mathbf{1}$
- ◆ in this case, the multiplicative inverse of  $a$  in  $Z_b$  is  $\mathbf{x}$

# Multiplicative group

A set of elements where multiplication  $\bullet$  is defined

- ◆ closure, associativity, identity & inverses
- ◆ multiplicative groups  $Z_n^*$ , defined w.r.t.  $Z_n$  (residues modulo  $n$ )
  - ◆ subsets of  $Z_n$  containing all integers that are relative prime to  $n$
  - ◆ if  $n$  is a prime number, then all non-zero elements in  $Z_n$  have an inverse
    - ◆  $Z_7^* = \{1, 2, 3, 4, 5, 6\}$ ,  $n = 7$
    - ◆  $2 \bullet 4 = 1 \pmod{7}$ ,  $3 \bullet 5 = 1 \pmod{7}$ ,  $6 \bullet 6 = 1 \pmod{7}$ ,  $1 \bullet 1 = 1 \pmod{7}$
  - ◆ if  $n$  is not prime, then not all integers in  $Z_n$  have an inverse
    - ◆  $Z_{10}^* = \{1, 3, 7, 9\}$ ,  $n = 10$
    - ◆  $3 \bullet 7 = 1 \pmod{10}$ ,  $9 \bullet 9 = 1 \pmod{10}$ ,  $1 \bullet 1 = 1 \pmod{10}$

# Order of a multiplicative group

Order of a group: cardinality of group

- ◆ multiplicative groups for  $Z_n^*$
- ◆ the totient function  $\phi(n)$  denotes the order of  $Z_n^*$ , i.e.,  $\phi(n) = |Z_n^*|$ 
  - ◆ if  $n = p$  is prime, then the order of  $Z_p^* = \{1, 2, \dots, p-1\}$  is  $p-1$ , i.e.,  $\phi(n) = p-1$ 
    - ◆ e.g.,  $Z_7^* = \{1, 2, 3, 4, 5, 6\}$ ,  $n = 7$ ,  $\phi(7) = 6$
  - ◆ if  $n$  is not prime,  $\phi(n) = n(1-1/p_1)(1-1/p_2)\dots(1-1/p_k)$ , where  $n = p_1^{e_1}p_2^{e_2}\dots p_k^{e_k}$ 
    - ◆ e.g.,  $Z_{10}^* = \{1, 3, 7, 9\}$ ,  $n = 10$ ,  $\phi(10) = 4$
- ◆ if  $n = pq$ , where  $p$  and  $q$  are distinct primes, then  $\phi(n) = (p-1)(q-1)$ 
  - ◆ difficult problem: given  $n = pq$ , where  $p, q$  are primes, find  $p$  and  $q$  or  $\phi(n)$

# Fermat's Little Theorem

## Theorem

If  $p$  is a prime, then for each nonzero  $x$  in  $\mathbb{Z}_p$ , we have  $x^{p-1} \bmod p = 1$

◆ example ( $p = 5$ ):

$$1^4 \bmod 5 = 1$$

$$2^4 \bmod 5 = 16 \bmod 5 = 1$$

$$3^4 \bmod 5 = 81 \bmod 5 = 1$$

$$4^4 \bmod 5 = 256 \bmod 5 = 1$$

## Corollary

If  $p$  is a prime, then the multiplicative inverse of each non-zero residue  $x$  in  $\mathbb{Z}_p$  is  $x^{p-2} \bmod p$

◆ proof:  $x(x^{p-2} \bmod p) \bmod p = xx^{p-2} \bmod p = x^{p-1} \bmod p = 1$

# Euler's Theorem

## Theorem

For each element  $x$  in  $Z_n^*$ , we have  $x^{\phi(n)} \bmod n = 1$

- ◆ example ( $n = 10$ )

- ◆  $Z_{10}^* = \{1, 3, 7, 9\}$ ,  $n = 10$ ,  $\phi(10) = 4$

- ◆  $3^{\phi(10)} \bmod 10 = 3^4 \bmod 10 = 81 \bmod 10 = 1$

- ◆  $7^{\phi(10)} \bmod 10 = 7^4 \bmod 10 = 2401 \bmod 10 = 1$

- ◆  $9^{\phi(10)} \bmod 10 = 9^4 \bmod 10 = 6561 \bmod 10 = 1$

# Computing in the exponent

For the multiplicative group  $Z_n^*$ , we can reduce the exponent modulo  $\phi(n)$

- ◆  $x^y \bmod n = x^{k\phi(n) + r} \bmod n = (x^{\phi(n)})^k x^r \bmod n = x^{r \bmod \phi(n)} \bmod n$

Corollary: For  $Z_p^*$ , we can reduce the exponent modulo  $p-1$

- ◆ example

- ◆  $Z_{10}^* = \{1, 3, 7, 9\}$ ,  $n = 10$ ,  $\phi(10) = 4$

- ◆  $3^{1590} \bmod 10 = 3^{1590 \bmod 4} \bmod 10 = 3^2 \bmod 10 = 9$

- ◆ how about  $2^8 \bmod 10$ ?

- ◆ example

- ◆  $Z_p^* = \{1, 2, \dots, p-1\}$ ,  $p = 19$ ,  $\phi(19) = 18$

- ◆  $15^{39} \bmod 19 = 15^{39 \bmod 18} \bmod 19 = 15^3 \bmod 19 = 12$

# Powers

Let  $p$  be a prime

- ◆ the sequences of successive powers of the elements in  $\mathbb{Z}_p^*$  exhibit repeating subsequences
- ◆ the sizes of the repeating subsequences and the number of their repetitions are the divisors of  $p - 1$
- ◆ example,  $p = 7$

$x$	$x^2$	$x^3$	$x^4$	$x^5$	$x^6$
1	1	1	1	1	1
2	4	1	2	4	1
3	2	6	4	5	1
4	2	1	4	2	1
5	4	6	2	3	1
6	1	6	1	6	1

# The Discrete Log problem & its applications

# The discrete logarithm problem

## Setting

- ◆ if  $p$  be an odd prime, then  $G = (Z_p^*, \cdot)$  is a cyclic group of order  $p - 1$ 
  - ◆  $Z_p^* = \{1, 2, 3, \dots, p-1\}$ , generated by some  $g$  in  $Z_p^*$ 
    - ◆ for  $i = 0, 1, 2, \dots, p-2$ , the process  **$g^i \bmod p$**  produces all elements in  $Z_p^*$
  - ◆ for any  $x$  in the group, we have that  **$g^k \bmod p = x$** , for some integer  $k$
  - ◆  $k$  is called the **discrete logarithm** (or  $\log$ ) of  $x \pmod{p}$

## Example

- ◆  $(Z_{17}^*, \cdot)$  is a cyclic group  $G$  with order 16, 3 is the generator of  $G$  and  $3^{16} = 1 \bmod 17$
- ◆ let  $k = 4$ ,  $3^4 = 13 \bmod 17$  (which is easy to compute)
- ◆ the inverse problem: if  $3^k = 13 \bmod 17$ , what is  $k$ ? what about **large  $p$** ?

# Computational assumption

## Discrete-log setting

- ◆ cyclic  $G = (Z_p^*, \cdot)$  of order  $p - 1$  generated by  $g$ , prime  $p$  of length  $t$  ( $|p| = t$ )

## Problem

- ◆ given  $G, g, p$  and  $x$  in  $Z_p^*$ , compute the discrete log  $k$  of  $x \pmod{p}$

## Discrete log assumption

- ◆ for groups of specific structure, **solving the discrete log problem is infeasible**
- ◆ any efficient algorithm finds discrete logs negligibly often ( $\text{prob} = 2^{-t/2}$ )

## Brute force attack

- ◆ cleverly enumerate and **check  $O(2^{t/2})$  solutions**

# ElGamal encryption

Assumes discrete-log setting (cyclic  $G = (Z_p^*, \cdot) = \langle g \rangle$ , prime  $p$ , message space  $Z_p$ )

## Gen

- ◆ secret key: random number  $x \in Z_p^*$       public key:  $A = g^x \bmod p$ , along w/  $G, g, p$

## Enc

- ◆ pick a fresh random  $r \in Z_p^*$  and set  $R = A^r (= g^{xr})$
- ◆ send ciphertext     **$\text{Enc}_{PK}(m) = (c_1, c_2)$**       where  **$c_1 = g^r$ ,  $c_2 = m \cdot R \bmod p$**

## Dec

- ◆  **$\text{Dec}_{SK}(c_1, c_2) = c_2 (1/c_1^x) \bmod p$**       where  **$c_1^x = g^{xr}$**

Security is based on **Computational Diffie-Hellman** (CDH) assumption

- ◆ given  $(g, g^a, g^b)$  it is hard to compute  $g^{ab}$

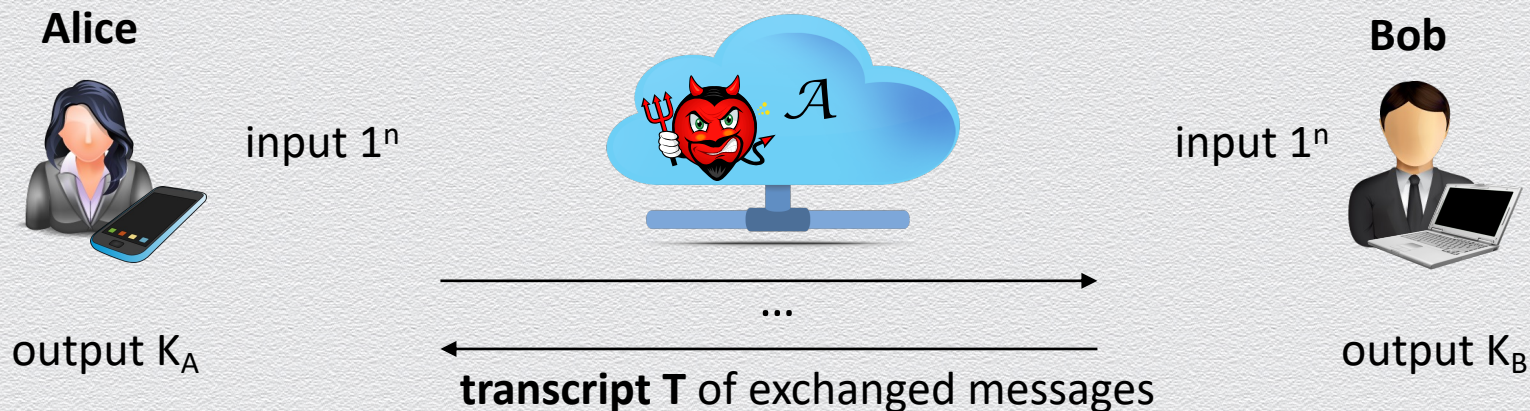

A signature scheme can be also derived based on above discussion

# Application: Key-agreement (KA) scheme

Alice and Bob want to securely establish a **shared key** for secure chatting over an **insecure** line

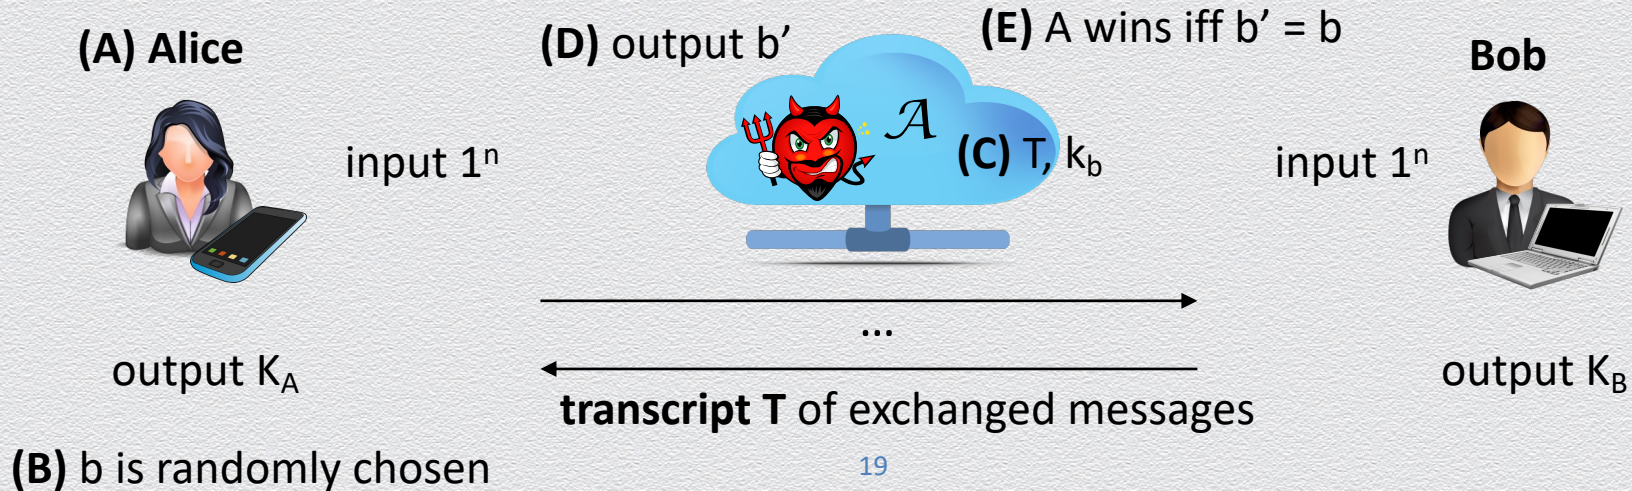

- ◆ instead of meeting in person in a secret place, they want to use the insecure line...
- ◆ KA scheme: they run a key-agreement protocol  $\Pi$  to contribute to a **shared key  $K$**
- ◆ correctness:  $K_A = K_B = K$
- ◆ security: no PPT adversary  $\mathcal{A}$ , given  $T$ , can distinguish  $K$  from a trully random one

# Key agreement: Game-based security definition

- ◆ scheme  $\Pi(1^n)$  runs to generate  $K = K_A = K_B$  and transcript  $T$ ; random bit  $b$  is chosen
- ◆ adversary  $\mathcal{A}$  is given  $T$  and  $k_b$ ; if  $b = 1$ , then  $k_b = K$ , else  $k_b$  is random (both  $n$ -bit long)
- ◆  $\mathcal{A}$  outputs bit  $b'$  and wins if  $b' = b$
- ◆ then:  $\Pi$  is secure if no PPT  $\mathcal{A}$  has non-negligible advantage than guessing

# The Diffie-Hellman key-agreement protocol

Alice and Bob want to securely establish a **shared key** for secure chatting over an **insecure** line

- ◆ DH KA scheme  $\Pi$

- ◆ discrete log setting:  $p, g$  public, where  $\langle g \rangle = \mathbb{Z}_p^*$  and  $p$  prime

Alice

input  $1^n$

(1) randomly pick secret  $a$

(3) send  $g^a \bmod p$

(4) send  $g^b \bmod p$

(5) set  $K = g^{ab} \bmod p = (g^b \bmod p)^a \bmod p$

Bob

input  $1^n$

(2) randomly pick secret  $b$

(6) set  $K = g^{ab} \bmod p = (g^a \bmod p)^b \bmod p$

# Security

- ◆ discrete log assumption is necessary but not sufficient
- ◆ decisional DH assumption
  - ◆ given  $g$ ,  $g^a$  and  $g^b$ ,  $g^{ab}$  is computationally indistinguishable from uniform

# Authenticated Diffie-Hellman
