# 7. Abelian groups.

A. Ushakov

MA503, October 26, 2022

#### Contents

Today we discuss finitely generated abelian groups and related topics.

- Matrices.
- Elementary matrix operations.
- Special matrices.
- Product.
- Row echelon form.
- Elementary row/column operations.
- Smith normal form.
- Free abelian groups.
- Free abelian groups: classification.
- Change of basis for an abelian group.
- Subgroups of a free abelian group.
- Classification of finitely generated abelian groups.
- Algebraic structure of  $U_n$ .

### Matrix notation.

$$A = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1j} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2j} & \dots & a_{2n} \\ \vdots & \vdots & & \vdots & & \vdots \\ a_{i1} & a_{i2} & \dots & a_{ij} & \dots & a_{in} \\ \vdots & \vdots & & \vdots & & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mj} & \dots & a_{mn} \end{bmatrix}$$

$$Definition$$

$$An \ m \times n \ matrix \ A \ is \ a_{numbers} \ (or \ other \ objections)$$

$$\bullet \ A \ has \ m \ rows;$$

$$\bullet \ A \ has \ n \ columns;$$

An  $m \times n$  matrix A is an  $m \times n$  array of numbers (or other objects). In particular,

**Notation.**  $(a_{ij})$  or  $(a_{ij})_{m \times n}$  – defines a matrix with entries  $a_{ij}$ .

### Definition

We say that matrices  $A=(a_{ij})_{m\times n}$  and  $B=(b_{ij})_{m\times n}$  are equal if they have the same entries, i.e.,  $a_{ii} = b_{ii}$  for each i, j.

# Elementary operations on matrices.

Consider two  $m \times n$  matrices  $A = (a_{ij})_{m \times n}$  and  $B = (b_{ij})_{m \times n}$  and a constant (scalar) k.

The sum of A and B is a new matrix  $C = A + B = (a_{ij} + b_{ij})_{m \times n}$ .

Example.

$$\begin{bmatrix} 2 & 3 & 1 \\ 0 & 6 & -3 \\ 2 & 1 & 4 \end{bmatrix} + \begin{bmatrix} 1 & -3 & 2 \\ 2 & 2 & 1 \\ 7 & -2 & 5 \end{bmatrix} = \begin{bmatrix} 3 & 0 & 3 \\ 2 & 8 & -2 \\ 9 & -1 & 9 \end{bmatrix}$$

**Scalar product** of k and A is a new matrix  $kA = (ka_{ij})_{m \times n}$ .

Example.

$$2\begin{bmatrix} 2 & 3 & 1 \\ 0 & -1 & -3 \\ 2 & 1 & 4 \end{bmatrix} = \begin{bmatrix} 4 & 6 & 2 \\ 0 & -2 & -6 \\ 4 & 1 & 8 \end{bmatrix}$$

# Special matrices.

$$I = \begin{bmatrix} 1 & 0 & 0 & \dots & 0 & 0 \\ 0 & 1 & 0 & \dots & 0 & 0 \\ 0 & 0 & 1 & & & 0 \\ \vdots & \vdots & & \ddots & & \vdots \\ 0 & 0 & & & 1 & 0 \\ 0 & 0 & 0 & \dots & 0 & 1 \end{bmatrix}$$

### Definition

The  $n \times n$  identity matrix  $I_n$  is the matrix  $(\delta_{ij})_{n \times n}$ , where  $\delta_{ij}$  is the Kronecker delta defined as follows:

1 if i = i.

$$\delta_{ij} = \begin{cases} 1 & \text{if } i = j, \\ 0 & \text{if } i \neq j. \end{cases}$$

### **Definition**

**Zero**  $m \times n$  **matrix** is defined by  $(0)_{m \times n}$ .

### Definition

A column matrix is an  $m \times 1$  matrix.

#### Definition

A row matrix is an  $1 \times n$  matrix.

An  $m \times n$  matrix can be viewed as

- a system of *m* rows,
- a system of n columns.

### Product of matrices

**Product of matrices**  $A = (a_{ij})_{m \times n}$  and  $B = (b_{ij})_{n \times k}$  is a new matrix  $C = (c_{ij})_{m \times k}$  defined by  $c_{ij} = a_{i1}a_{1j} + \ldots + a_{in}a_{nj}$  which can be recognized as dot product of the *i*th row in A and jth column in B

$$\begin{bmatrix} a_{11} & a_{12} & \dots & a_{1j} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2j} & \dots & a_{2n} \\ \vdots & \vdots & & \vdots & & \vdots \\ a_{i1} & a_{i2} & \dots & a_{ij} & \dots & a_{in} \\ \vdots & \vdots & & \vdots & & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mj} & \dots & a_{mn} \end{bmatrix} \cdot \begin{bmatrix} b_{11} & b_{12} & \dots & b_{1j} & \dots & b_{1k} \\ b_{21} & b_{22} & \dots & b_{2j} & \dots & b_{2k} \\ \vdots & \vdots & & \vdots & & \vdots \\ b_{i1} & b_{i2} & \dots & b_{ij} & \dots & b_{ik} \\ \vdots & \vdots & & \vdots & & \vdots \\ b_{n1} & b_{n2} & \dots & b_{nj} & \dots & b_{nk} \end{bmatrix} = (c_{ij})_{m \times k}.$$

In general,  $AB \neq BA$ .

For instance,

$$\begin{bmatrix} 1 & 2 \\ -1 & 3 \\ 0 & 5 \end{bmatrix} \cdot \begin{bmatrix} -3 & 1 \\ 1 & 2 \end{bmatrix} = \begin{bmatrix} -1 & 5 \\ 6 & 5 \\ 5 & 10 \end{bmatrix}$$

The product below makes no sense (incompatible dimensions)

$$\left[\begin{array}{cc} -3 & 1 \\ 1 & 2 \end{array}\right] \cdot \left[\begin{array}{cc} 1 & 2 \\ -1 & 3 \\ 0 & 5 \end{array}\right]$$

### Matrices: row echelon form

#### Definition

A matrix is in row echelon form if

- 1 all nonzero rows (rows with at least one nonzero element) are above any rows of all zeroes (all zero rows, if any, belong at the bottom of the matrix), and
- ② the leading coefficient (the first nonzero number from the left, also called the pivot) of a nonzero row is always strictly to the right of the leading coefficient of the row above it (some texts add the condition that the leading coefficient must be 1).

For instance, the following matrix is in row echelon form:

Many properties of matrices (e.g. the rank) can be easily deduced from their row echelon form.

$$\left[\begin{array}{cccccc} \mathbf{1} & a_0 & a_1 & a_2 & a_3 \\ 0 & 0 & \mathbf{2} & a_4 & a_5 \\ 0 & 0 & 0 & \mathbf{1} & a_6 \end{array}\right]$$

**Gaussian elimination** (or row reduction) is a process of reducing a given matrix to a row echelon form.

# Matrices: elementary row/column operations

### (Elementary row operations)

- Row addition: a row can be replaced by the sum of that row and an integer-multiple of another row.
- Row switching: switch two rows.
- Row inversion: multiply a row by -1.

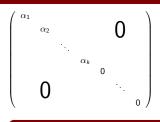

We use elementary row operations to reduce the matrix to a row echelon form.

### (Elementary column operations)

- Column addition: a column can be replaced by the sum of that column and a integer-multiple of another column.
- Column switching: switch two column.
- Column inversion: multiply a column by -1.

Elementary column operations correspond to change of basis, discussed later.

### Smith normal form

### Definition

A diagonal  $k \times n$  matrix shown on the left is in **Smith normal form** if

- $\alpha_i \geq 0$
- $\bullet$   $\alpha_i \mid \alpha_{i+1}$ .

### Proposition

Any matrix M with entries from  $\mathbb Z$  can be transformed into Smith normal form using elementary row and column operations.

First, it is proved that any matrix M can be transformed into a matrix of the form shown on the right, where  $\alpha_1$  divides every  $y_{i,j}$ . Then the proof goes by induction on dimensions of M.

$$\left( \begin{array}{ccccccc} \alpha_1 & 0 & \dots & 0 \\ 0 & y_{2,2} & \dots & y_{2,n} \\ \vdots & \vdots & & \vdots \\ 0 & y_{k,2} & \dots & y_{k,n} \end{array} \right)$$

### (Uniqueness of Smith normal form)

There are infinitely many ways to transform a given M to a Smith normal form. The result is always the same.

# Smith normal form: example

Consider the matrix below (denote columns  $x_1, x_2, x_3$  and rows  $y_1, y_2, y_3$ )

$$\left(\begin{array}{ccc}
6 & 0 & 0 \\
0 & 8 & 0 \\
0 & 0 & 10
\end{array}\right)$$

Applying elementary column/row operations we get matrices:

$$\stackrel{y_1 \leftarrow y_1 + y_2}{\to} \left( \begin{array}{ccc} 6 & 8 & 0 \\ 0 & 8 & 0 \\ 0 & 0 & 10 \end{array} \right) \stackrel{x_2 \leftarrow x_1 + x_2}{\to} \left( \begin{array}{ccc} 6 & 2 & 0 \\ 0 & 8 & 0 \\ 0 & 0 & 10 \end{array} \right) \stackrel{x_1 \leftrightarrow x_2}{\to} \left( \begin{array}{ccc} 2 & 6 & 0 \\ 8 & 0 & 0 \\ 0 & 0 & 10 \end{array} \right)$$

$$\stackrel{y_2 \leftarrow y_2 - 4y_1}{\Rightarrow} \left( \begin{array}{ccc} 2 & 6 & 0 \\ 0 & -24 & 0 \\ 0 & 0 & 10 \end{array} \right) \stackrel{x_2 \leftarrow x_2 - 3x_1}{\Rightarrow} \left( \begin{array}{ccc} 2 & 0 & 0 \\ 0 & -24 & 0 \\ 0 & 0 & 10 \end{array} \right) \stackrel{x_2 \leftarrow -x_2}{\rightarrow} \left( \begin{array}{ccc} 2 & 0 & 0 \\ 0 & 24 & 0 \\ 0 & 0 & 10 \end{array} \right)$$

In a similar way we get

$$\rightarrow \left(\begin{array}{ccc} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 120 \end{array}\right)$$

The obtained matrix is in the Smith normal form.

# Smith normal form: more examples

#### Example 1.

$$\begin{pmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \\ 2 & 3 & 1 \end{pmatrix} \rightarrow \begin{pmatrix} 1 & 2 & 3 \\ 0 & -5 & -7 \\ 0 & -1 & -5 \end{pmatrix} \rightarrow \begin{pmatrix} 1 & 0 & 0 \\ 0 & -5 & -7 \\ 0 & -1 & -5 \end{pmatrix} \rightarrow \begin{pmatrix} 1 & 0 & 0 \\ 0 & 5 & 7 \\ 0 & 1 & 5 \end{pmatrix}$$
$$\rightarrow \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 5 \\ 0 & 5 & 7 \end{pmatrix} \rightarrow \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 5 \\ 0 & 0 & -18 \end{pmatrix} \rightarrow \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 18 \end{pmatrix}$$

#### Example 2.

$$\begin{pmatrix} 6 & -2 & 6 \\ -12 & 6 & -6 \\ 12 & -4 & 42 \end{pmatrix} \rightarrow \begin{pmatrix} -2 & 6 & 6 \\ 6 & -12 & -6 \\ -4 & 12 & 42 \end{pmatrix} \rightarrow \begin{pmatrix} 2 & -6 & -6 \\ 6 & -12 & -6 \\ -4 & 12 & 42 \end{pmatrix} \rightarrow \begin{pmatrix} 2 & 0 & 0 \\ 6 & 6 & 12 \\ -4 & 0 & 30 \end{pmatrix}$$
 
$$\rightarrow \begin{pmatrix} 2 & 0 & 0 \\ 0 & 6 & 12 \\ 0 & 0 & 30 \end{pmatrix} \rightarrow \begin{pmatrix} 2 & 0 & 0 \\ 0 & 6 & 0 \\ 0 & 0 & 30 \end{pmatrix}$$

## Free abelian groups

#### Definition

An abelian group G is called a **free abelian group** if it has a subset  $X \subseteq G$  such that  $G = \langle X \rangle$  and for all distinct  $x_1, \ldots, x_n \in X$  and  $\alpha_1, \ldots, \alpha_n \in \mathbb{Z}$ 

$$\alpha_1 x_1 + \ldots + \alpha_n x_n = 0 \quad \Leftrightarrow \quad \alpha_1 = \ldots = \alpha_n = 0.$$

Such set X is called a **free basis** for G.

- The trivial group is free abelian.
- $\mathbb{Z}$  is a free abelian group. It has two free bases:  $\{1\}$  and  $\{-1\}$ .
- $\mathbb{Z}^n$  is a free abelian group. The standard basis for  $\mathbb{Z}^n$  is  $\{e_1,\ldots,e_n\}$ , where

$$\begin{cases} e_1 = (1,0,0,\ldots,0) \\ e_2 = (0,1,0,\ldots,0) \\ \ldots \\ e_n = (0,0,0,\ldots,1). \end{cases}$$

Z<sub>5</sub> is not free abelian because 5a = Z<sub>5</sub> 0 for every a ∈ Z<sub>5</sub>. Therefore, no element a ∈ Z<sub>5</sub> can be a part of a free basis for Z<sub>5</sub>.

If  $X = \{x_1, \dots, x_n\}$  is a free basis for abelian G, then every  $g \in G$  can be uniquely expressed as  $g = \alpha_1 x_1 + \dots + \alpha_n x_n$ .

$$\alpha_1 x_1 + \ldots + \alpha_n x_n = \beta_1 x_1 + \ldots + \beta_n x_n \quad \Leftrightarrow \quad (\beta_1 - \alpha_1) x_1 + \ldots + (\beta_n - \alpha_n) x_n = 0.$$

# Free abelian groups: classification

If  $X = \{x_1, \dots, x_n\}$  is a basis of a free abelian group G. Then  $G \simeq \mathbb{Z}^n$ .

 $\varphi: \mathbb{Z}^n \to G$  defined by  $(\alpha_1, \dots, \alpha_n) \stackrel{\varphi}{\mapsto} \alpha_1 x_1 + \dots + \alpha_n x_n$  is an isomorphism.

 $\mathbb{Z}^m \simeq \mathbb{Z}^n$  if and only if m = n.

 $\mathsf{Hom}(\mathbb{Z}^n,\mathbb{Z}_2)=2^n.$ 

### Corollary

All free bases for G have the same size n. The number n is called the rank of G.

# Change of basis for an abelian group

Suppose  $G=\langle x_1,\ldots,x_n\rangle$  is abelian. We treat  $x_1,\ldots,x_n$  as a sequence here. Then

**(B1)** 
$$\{\ldots, x_{i-1}, x_i + cx_j, x_{i+1}, \ldots\}$$
 is a basis for  $G$ .

$$egin{align*} v &= lpha_1 x_1 + \ldots + lpha_n x_n & \text{in original basis} \ &= lpha_1 x_1 + \ldots + lpha_i (x_i + c x_j) + \ldots + (lpha_j - c lpha_i) x_j + lpha_n x_n & \text{in new basis.} \ \end{align*}$$

**(B2)** 
$$\{..., x_{i-1}, x_j, x_{i+1}, ..., x_{j-1}, x_i, x_{j+1}, ...\}$$
 is a basis for  $G$ .

$$egin{align*} v &= lpha_1 x_1 + \ldots + lpha_n x_n & \text{in original basis} \ &= lpha_1 x_1 + \ldots + lpha_j x_j + \ldots + lpha_i x_i + \ldots + lpha_n x_n & \text{in new basis}. \ \end{aligned}$$

**(B3)**  $\{..., x_{i-1}, -x_i, x_{i+1}, ...\}$  is a basis for *G*.

$$v = \alpha_1 x_1 + \ldots + \alpha_n x_n$$
 in original basis 
$$= \alpha_1 x_1 + \ldots - \alpha_i (-x_i) + \ldots + + \alpha_n x_n$$
 in new basis.

 $\mathbb{Z}^n$  has infinitely many bases (if  $n \geq 2$ ). The standard basis is the set  $\{e_1, \ldots, e_n\}$ .

Transformations (B1), (B2), (B3) are reversible. Hence, the following are equivalent

- we can transform a basis  $\{x_1, \ldots, x_n\}$  into a basis  $\{y_1, \ldots, y_n\}$ ,
- we can transform a basis  $\{y_1, \ldots, y_n\}$  into a basis  $\{x_1, \ldots, x_n\}$ .

# Changing to any basis

#### $\mathsf{Theorem}$

Every free basis for  $\mathbb{Z}^n$  can be obtained by a sequence of transformations (B1), (B2), (B3) starting from the standard basis  $\{e_1, \ldots, e_n\}$ .

$$\begin{pmatrix} x_{11} & x_{12} & \dots & x_{1n} \\ x_{21} & x_{22} & \dots & x_{2n} \\ \vdots & \vdots & & \vdots \\ x_{n1} & x_{n2} & \dots & x_{nn} \end{pmatrix}$$

 $\begin{pmatrix} x_{11} & x_{12} & \dots & x_{1n} \\ x_{21} & x_{22} & \dots & x_{2n} \\ \vdots & \vdots & & \vdots \\ x_{n1} & x_{n2} & \dots & x_{nn} \end{pmatrix}$  For a free basis  $\{x_1, \dots, x_n\}$  construct a matrix M of row-vectors  $\{x_1, \dots, x_n\}$ . We prove that we can transform the basis  $\{x_1, \dots, x_n\}$  into  $\{e_1, \dots, e_n\}$  and its matrix to I.

Hence, we can get the matrix on the right

$$\begin{pmatrix}
1 & 0 & \dots & 0 \\
0 & y_{22} & \dots & y_{2n} \\
\vdots & \vdots & & \vdots \\
0 & y_{n2} & \dots & y_{nn}
\end{pmatrix}$$

$$(0, y_{12}, \ldots, y_{1n}) = \beta_2 y_2 + \ldots + \beta_n y_n$$
 for some  $\beta_1, \ldots, \beta_n \in \mathbb{Z}$ .

 $\begin{pmatrix} 1 & 0 & \dots & 0 \\ 0 & y_{22} & \dots & y_{2n} \\ \vdots & \vdots & & \vdots \\ 0 & y_{2n} & \dots & y_{2n} \end{pmatrix} \qquad (0, y_{12}, \dots, y_{1n}) = \beta_2 y_2 + \dots + \beta_n y_n \text{ for some } \beta_1, \dots, \beta_n \in \mathbb{Z}.$  Hence, using (B1) transformations we can get the matrix on the left.

Proceed by induction to get 1.

# Subgroup of a free abelian group is free abelian

Fix  $H \leq \mathbb{Z}^n$ .

If 
$$\overline{a}=(a_1,\ldots),\overline{b}=(b_1,\ldots)\in H$$
 with  $a_1,b_1\neq 0$ , then there is  $(\gcd(a_1,b_1),\ldots)\in H$ .

$$\gcd(a_1,b_1)=\alpha a_1+\beta b_1$$
 for some  $\alpha,\beta\in\mathbb{Z}$ . Hence,  $\alpha \overline{a}+\beta \overline{b}=(\gcd(a_1,b_1),\ldots)\in H$ .

 $H \leq \mathbb{Z}^n$  is free abelian of rank at most n.

#### Induction on n.

- Find any  $\overline{a} = (a_1, \ldots) \in H$  with the least positive  $a_1$ .
- Let  $H_1 = \{ \overline{r} \in H \mid \overline{r} = (0, r_1, \ldots) \} \le H$ . Dropping the first zero,  $H_1$  is a subgroup of  $\mathbb{Z}^{n-1}$ . By induction,  $H_1$  has a free basis  $\{\overline{r}_1, \ldots, \overline{r}_m\}$ .
- Then for any  $\overline{b}=(b_1,\ldots)\in H$  we have  $b_1=qa_1$  and  $\overline{b}=q\overline{a}+\overline{r}$  for some  $\overline{r}\in H_1$ . Notice that g is uniquely defined.
- Hence,  $\{\overline{a}, \overline{r}_1, \dots, \overline{r}_m\}$  is a free basis of H.

The obtained system of row vectors  $\{\overline{a}, \overline{r}_1, \dots, \overline{r}_m\}$  defines a matrix  $M_H$ . By construction,  $M_H$  is in row echelon form.

Our next goal: Show that for every  $H \leq \mathbb{Z}^n$  we can find a basis for  $\mathbb{Z}^n$  in which H has a very simple description. We can manipulate with the description of H as follows:

- change basis for H (elementary row transformations of  $M_H$ ),
- change basis for  $\mathbb{Z}^n$  (elementary column transformations of  $M_H$ ).

# Changing bases for $\mathbb{Z}^n$ and H

Applying transformations (B1), (B2), (B3) to the basis of H we can get any other basis of H. Each transformation changes  $M_H$  as follows:

- (B1) performs row addition.
- (B2) performs row switching.
- (B3) performs row inversion.

Applying transformations (B1), (B2), (B3) to the basis of  $\mathbb{Z}^n$  we can get any other basis of  $\mathbb{Z}^n$ . Each transformation changes  $M_H$  as follows:

- (B1) performs column addition.
- (B2) performs column switching.
- (B3) performs column inversion.

Changing the bases for  $\mathbb{Z}^n$  and H we can transform  $M_H$  to its Smith normal form.

 $M_H$  encodes the generators of H. Thus, for any  $H \leq \mathbb{Z}^n$  we can find a basis for  $\mathbb{Z}^n$  such that

$$H = \langle \alpha_1 e_1, \ldots, \alpha_k e_k, 0 \ldots \rangle,$$

where  $\alpha_i \mid \alpha_{i+1}$ .

# Abelian groups: classification

Let  $G = \langle x_1, \dots, x_n \rangle$  be an abelian group.  $\bar{r} = (\alpha_1, \dots, \alpha_n)$  is called a **relation** in G if  $\alpha_1 x_1 + \dots + \alpha_n x_n = 0$ .

The set of relations R in G is a subgroup of  $\mathbb{Z}^n$ .

- 0 is a relation;
- if  $\overline{r}$  is a relation, then  $-\overline{r}$  is a relation;
- if  $\overline{r}_1, \overline{r}_2$  are relations, then  $\overline{r}_1 + \overline{r}_2$  is a relation.

We've seen before that changing the bases we can get a very easy description of R. As a consequence we get  $\{y_1, \ldots, y_n\}$  for G in which

$$\alpha_1 y_1 = 0, \alpha_2 y_2 = 0, \dots, \alpha_k y_k = 0$$

#### **Theorem**

If G is a finitely generated abelian group, then  $G \simeq \mathbb{Z}_{\alpha_1} \times \ldots \times \mathbb{Z}_{\alpha_k} \times \mathbb{Z} \times \ldots \times \mathbb{Z}$ , where  $\alpha_i \mid \alpha_{i+1}$ .

### Corollary

If G is a finitely generated abelian group, then

$$\mathsf{G}\simeq \mathbb{Z}_{p_1^{a_1}}\times \ldots \times \mathbb{Z}_{p_{\iota}^{a_k}}\times \mathbb{Z}\times \ldots \times \mathbb{Z},$$

where  $p_i$  are prime numbers (some of them can be equal) and  $a_i \in \mathbb{Z}$ .

20

# Classification of fg abelian groups: example

Suppose that G is an abelian group generated by  $x_1, x_2, x_3$  that are subject to the following relations:

$$r_1 = 6x_1 - 2x_2 + 6x_3 = 0$$
  
 $r_2 = -12x_1 + 6x_2 - 6x_3 = 0$   
 $r_3 = 12x_1 - 4x_2 + 42x_3 = 0$ .

Assuming that this set of relations is complete (all other relations follow from  $r_1, r_2, r_3$ ), express G as a direct product of cyclic groups.

Write down the relation matrix

$$\left[ \begin{array}{cccc}
6 & -2 & 6 \\
-12 & 6 & -6 \\
12 & -4 & 42
\end{array} \right]$$

and find its Smith normal form

$$\left[\begin{array}{ccc}
2 & 0 & 0 \\
0 & 6 & 0 \\
0 & 0 & 30
\end{array}\right]$$

Hence, the group is isomorphic to  $\mathbb{Z}_2 \times \mathbb{Z}_6 \times \mathbb{Z}_{30}$ .

# Algebraic structure of $U_n$

#### Theorem

The following holds:

- U<sub>2</sub> is trivial.
- $U_4 \simeq \mathbb{Z}_2$ .
- $U_{2^k} \simeq \mathbb{Z}_2 \times \mathbb{Z}_{2^{k-2}}$ .
- $U_{p^k} \simeq \mathbb{Z}_{p^{k-1}(p-1)}$  for an odd prime p.

#### Lemma

$$\gcd(n, m) = 1 \quad \Rightarrow \quad U_{nm} \simeq U_n \times U_m.$$

$$a \in U_{mn} \Leftrightarrow \gcd(a, mn) = 1 \Leftrightarrow \gcd(a, m) = 1 \Leftrightarrow a \in U_m$$
  
 $\gcd(a, n) = 1 \Leftrightarrow a \in U_m$ 

That defines a map  $\varphi: U_{mn} \to U_n \times U_m$  as  $a \mapsto (a, a)$ , which is an isomorphism.

### Corollary

If 
$$\mathsf{PPF}(n) = p_1^{k_1} \dots p_s^{k_s}$$
, then  $U_n \simeq U_{p_1^{k_1}} \times \dots \times U_{p_s^{k_s}}$ .
